1 A simple Gaussian location model

A

The joint prior over the mean parameter θ and precision parameter ω is:

$$p(\theta, \omega) \propto \omega^{(d+1)/2-1} \exp\left\{-\omega\frac{\kappa(\theta-\mu)^2}{2}\right\} \exp\left\{-\omega\frac{\eta}{2}\right\}$$

To get the marginal prior, we integrate out the parameter ω:

$$p(\theta) \propto \int_0^\infty \omega^{(d+1)/2-1} \exp\left\{-\omega\frac{\kappa(\theta-\mu)^2+\eta}{2}\right\}$$

$$\propto \left(\frac{\kappa(\theta-\mu)^2+\eta}{2}\right)^{-(d+1)/2}$$

$$= \left(\frac{\eta}{2} + \frac{\kappa(\theta-\mu)^2}{2}\right)^{-(d+1)/2}$$

$$= \left(1 + \frac{\kappa(\theta-\mu)^2}{\eta}\right)^{-(d+1)/2} \left(\frac{\eta}{2}\right)^{-(d+1)/2}$$

$$\propto \left(1 + \frac{\kappa(\theta-\mu)^2}{\eta}\right)^{-(d+1)/2}$$

$$= \left(1 + \frac{1}{d}\frac{d\kappa(\theta-\mu)^2}{\eta}\right)^{-(d+1)/2}$$

Let $\nu = d, m = \mu$ and $s = \sqrt{\eta/(d\kappa)}$, we have a Student t distribution with ν degrees of freedom and scale s:

$$p(\theta) \propto \left(1 + \frac{1}{\nu}\frac{(\theta-m)^2}{s^2}\right)^{-(\nu+1)/2}$$

B

The sampling model is:

$$(y_i \mid \theta, \omega) \sim N(\theta, 1/\omega)$$

where $y_1, \ldots, y_n$ are the datapoints, θ is the mean and ω is the precision. We have that the likelihood for all the datapoints can be written as:

$$p(\mathbf{y} \mid \theta, \omega) \propto \prod_{i=1}^{n} \omega^{1/2} \exp\left\{-\frac{1}{2}\omega(y_i - \theta)^2\right\}$$

$$= \omega^{n/2} \exp\left\{-\frac{1}{2}\omega \sum_{i=1}^{n}(y_i - \theta)^2\right\}$$

$$= \omega^{n/2} \exp\left\{-\frac{1}{2}\omega \left(\sum_{i=1}^{n} y_i^2 + \sum_{i=1}^{n} \theta^2 - 2\sum_{i=1}^{n} y_i \theta\right)\right\}$$

$$= \omega^{n/2} \exp\left\{-\frac{1}{2}\omega \left(\sum_{i=1}^{n} y_i^2 + n\theta^2 - 2n\overline{y}\theta + n\overline{y}^2 - n\overline{y}^2\right)\right\}$$

where $\overline{y} = \left(\sum_{i=1}^{n} y_i\right)/n$. Let $S_y = \sum_{i=1}^{n}(y_i - \overline{y})^2$, we have:

$$S_y = \sum_{i=1}^{n} y_i^2 + n\overline{y}^2 - 2\sum_{i=1}^{n} y_i \overline{y}$$

$$= \sum_{i=1}^{n} y_i^2 - n\overline{y}^2$$

Therefore, the likelihood is:

$$p(\mathbf{y} \mid \theta, \omega) = \omega^{n/2} \exp\left\{-\frac{1}{2}\omega \left[S_y + n(\theta^2 - 2\overline{y}\theta + \overline{y}^2)\right]\right\}$$

$$= \omega^{n/2} \exp\left\{-\frac{1}{2}\omega \left[S_y + n(\overline{y} - \theta)^2\right]\right\}$$

The posterior is proportional to the product of the likelihood and the prior:

$$p(\theta, \omega \mid \mathbf{y}) \propto \omega^{(d+1)/2-1} \exp\left\{-\omega \frac{\kappa(\theta - \mu)^2}{2}\right\} \exp\left\{-\omega \frac{\eta}{2}\right\}$$

$$\omega^{n/2} \exp\left\{-\frac{1}{2}\omega \left[S_y + n(\overline{y} - \theta)^2\right]\right\}$$

$$= \omega^{(d+n+1)/2-1} \exp\left\{-\omega \frac{\kappa(\theta - \mu)^2 + n(\theta - \overline{y})^2}{2}\right\} \exp\left\{-\omega \frac{\eta + S_y}{2}\right\}$$

We also have:

$$\kappa(\theta - \mu)^2 + n(\theta - \overline{y})^2 = \kappa\theta^2 + \kappa\mu^2 - 2\kappa\theta\mu + n\theta^2 + n\overline{y}^2 - 2n\theta\overline{y}$$
$$= (\kappa + n)\theta^2 - 2\theta(\kappa\mu + n\overline{y}) + (\kappa\mu^2 + n\overline{y}^2)$$
$$= (\kappa + n)\left(\theta^2 - 2\theta\frac{\kappa\mu + n\overline{y}}{\kappa + n} + \frac{(\kappa\mu + n\overline{y})^2}{(\kappa + n)^2}\right) - \frac{(\kappa\mu + n\overline{y})^2}{\kappa + n} + (\kappa\mu^2 + n\overline{y}^2)$$
$$= (\kappa + n)\left(\theta^2 - \frac{\kappa\mu + n\overline{y}}{\kappa + n}\right)^2 - \frac{(\kappa\mu + n\overline{y})^2}{\kappa + n} + (\kappa\mu^2 + n\overline{y}^2)$$

Therefore, the posterior is:

$$p(\theta, \omega \mid \mathbf{y}) \propto \omega^{(d^*+1)/2-1} \exp\left\{-\omega\frac{\kappa^*(\theta - \mu^*)^2}{2}\right\} \exp\left\{-\omega\frac{\eta^*}{2}\right\}$$

where:

$$d^* = d + n$$
$$\kappa^* = \kappa + n$$
$$\mu^* = \frac{\kappa\mu + n\overline{y}}{\kappa + n}$$

and

$$\eta^* = \eta + S_y - \frac{(\kappa\mu + n\overline{y})^2}{\kappa + n} + (\kappa\mu^2 + n\overline{y}^2)$$
$$= \eta + S_y + \frac{(\kappa + n)(\kappa\mu^2 + n\overline{y}^2) - \kappa^2\mu^2 - n^2\overline{y}^2 + 2\kappa n\mu\overline{y}}{\kappa + n}$$
$$= \eta + S_y + \frac{\kappa n\mu^2 + \kappa n\overline{y}^2 + 2\kappa n\mu\overline{y}}{\kappa + n}$$
$$= \eta + S_y + \frac{\kappa n(\mu + \overline{y})^2}{\kappa + n}$$

C

The conditional distribution is:

$$p(\theta \mid \mathbf{y}, \omega) \propto \exp\left\{-\omega\frac{\kappa^*(\theta - \mu^*)^2}{2}\right\}$$

We see that this is a Normal distribution with mean μ^* and variance $1/(\omega\kappa^*)$.

D

The marginal posterior of ω is:

$$p(\omega \mid \mathbf{y}) = \int_{-\infty}^{\infty} p(\omega, \theta \mid \mathbf{y}) d\theta$$

$$\propto \omega^{(d^*+1)/2-1} \exp\left\{-\omega\frac{\eta^*}{2}\right\} \int_{-\infty}^{\infty} \exp\left\{-\omega\frac{\kappa^*(\theta - \mu^*)^2}{2}\right\} d\theta$$

$$\propto \omega^{(d^*+1)/2-1} \exp\left\{-\omega\frac{\eta^*}{2}\right\} \qquad \text{(Gaussian integral)}$$

We see that this marginal is a Gamma distribution with parameter $(d^*/2, \eta^*/2)$.

E

The marginal posterior of θ is:

$$p(\theta \mid \mathbf{y}) = \int_{0}^{\infty} p(\theta, \omega \mid \mathbf{y}) d\omega$$

$$= \int_{0}^{\infty} \omega^{(d^*+1)/2-1} \exp\left\{-\omega\frac{\kappa^*(\theta - \mu^*)^2 + \eta^*}{2}\right\}$$

This is the same integral in part A. By the results in A, we can see that this marginal is a Student t distribution with parameters $\nu = d^*, m = \mu^*$ and $s = \sqrt{\eta^*/(\kappa^* d^*)}$.

F

FALSE. As κ approaches 0, the Normal prior on θ approaches a point distribution but the density at that point is infinite. As d and η approach 0, the Gamma prior on ω also approach a point distribution with infinite density.

G

TRUE. By the results in D and E, we see that when the prior parameters approach 0, the posterior parameters are not 0 then $p(\theta \mid \mathbf{y})$ and $p(\omega \mid \mathbf{y})$ are valid distribution.

H

The classical frequentest confidence interval for θ is:

$$\overline{y} \pm t^* \frac{\sqrt{S_y}}{\sqrt{n(n-1)}}$$

As the prior parameters κ, d, η approach 0, we have the Bayesian credible interval for θ is:

$$m \pm t^* s$$

from the results in B and E, we have

$$m = \mu^* = \bar{y}$$

and

$$s = \sqrt{\eta^*/(\kappa d^*)} = \sqrt{\frac{S_y}{n^2}}$$

We see that this is different from the classical confidence interval.

2 The conjugate Gaussian linear model

A

$$
\begin{aligned}
p(\beta, \mathbf{y} \mid \omega) &= p(\beta \mid \omega) p(\mathbf{y} \mid \beta, \omega) \\
&= N(\beta; m, (\omega K)^{-1}) N(\mathbf{y}; X\beta, (\omega \Lambda)^{-1}) \\
&\propto \omega^{p/2} K^{p/2} \exp\left\{ \frac{1}{2}(\beta - m)^T \omega K (\beta - m) \right\} \\
&\quad \omega^{n/2} \Lambda^{n/2} \exp\left\{ \frac{1}{2}(\mathbf{y} - X\beta)^T \omega \Lambda (\mathbf{y} - X\beta) \right\} \\
&= \omega^{(n+p)/2} K^{p/2} \Lambda^{n/2} \exp\left\{ \frac{1}{2}\omega E \right\}
\end{aligned}
$$

where we have let E be the sum of two quadratic forms inside the exponent:

$$
\begin{aligned}
E &= \beta^T K \beta - 2\beta^T K m + m^T K m + \mathbf{y}^T \Lambda \mathbf{y} - 2\beta^T X^T \Lambda \mathbf{y} + \beta^T X^T \Lambda X \beta \\
&= \begin{pmatrix} \beta \\ \mathbf{y} \end{pmatrix}^T \begin{pmatrix} K + X^T \Lambda X & -X^T \Lambda \\ -\Lambda^T X & \Lambda \end{pmatrix} \begin{pmatrix} \beta \\ \mathbf{y} \end{pmatrix} + \text{const}
\end{aligned}
$$

where we have ignored linear terms in β and $\mathbf{y}$. We then have that (given ω) β and $\mathbf{y}$ are jointly Normal:

$$
\begin{pmatrix} \beta \\ \mathbf{y} \end{pmatrix} \sim N\left(\begin{pmatrix} m \\ Xm \end{pmatrix}, \begin{pmatrix} \omega K + \omega X^T \Lambda X & -\omega X^T \Lambda \\ -\omega \Lambda^T X & \omega \Lambda \end{pmatrix}^{-1} \right)
$$

Using the conditional Normal equations, we have that $p(\beta \mid \mathbf{y}, \omega)$ is Normal with mean:

$$
\begin{aligned}
m^* &= m + (\omega K + \omega X^T \Lambda X)^{-1}(-\omega X^T \Lambda)(Xm - \mathbf{y}) \\
&= m + (K + X^T \Lambda X)^{-1}(-X^T \Lambda)(Xm - \mathbf{y})
\end{aligned}
$$

and variance:

$$(\omega K^*)^{-1} = (\omega K + \omega X^T \Lambda X)^{-1}$$

B

We have that $p(\mathbf{y} \mid \omega)$ is Normal with mean Xm and variance:

$$\begin{aligned}\mathrm{var}(X\beta + \epsilon) &= X\mathrm{var}(\beta)X^T + (\omega\Lambda)^{-1} \\ &= X(\omega K)^{-1}X^T + (\omega\Lambda)^{-1}\end{aligned}$$

We then have:

$$p(\omega \mid \mathbf{y}) \propto p(\omega)p(\mathbf{y} \mid \omega)$$

$$\propto \omega^{d/2-1} \exp\left\{-\omega\frac{\eta}{2}\right\} \omega^{n/2} \exp\left\{-\omega\frac{1}{2}(\mathbf{y} - Xm)^T(XK^{-1}X^T + \Lambda^{-1})^{-1}(\mathbf{y} - Xm)\right\}$$

We see that this distribution is Gamma with parameter $d^*/2$ and $\eta^*/2$ where:

$$\begin{aligned}d^* &= d + n \\ \eta^* &= \eta + (\mathbf{y} - Xm)^T(XK^{-1}X^T + \Lambda^{-1})^{-1}(\mathbf{y} - Xm)\end{aligned}$$

C

$$p(\beta \mid \mathbf{y}) = \int_0^\infty p(\beta \mid \mathbf{y}, \omega)p(\omega \mid \mathbf{y})d\omega$$

$$\int_0^\infty \omega^{(d+n+p)/2} \exp\left\{-\frac{\omega}{2}(\beta - m^*)^T K^*(\beta - m^*)\right\} \exp\left\{-\frac{\omega}{2}\eta^*\right\}$$

This is an integral over a Normal gamma distribution. From previous results, we see that it is a Student t distribution:

$$p(\beta \mid \mathbf{y}) = \left(1 + \frac{1}{\nu}\frac{(\beta - \mu)^2}{s^2}\right)^{-(\nu+1)/2}$$

where

$$\begin{aligned}\nu &= d + n + p \\ \mu &= m^* \\ s &= \sqrt{\eta^*}\end{aligned}$$

D

Code: blr.r

A heavy-tailed error model

A

With the Gamma parameters λ integrated out, the marginal distribution over y_i is Student t. It has a wider tail and is more robust to outliers.

B

$$
\begin{aligned}
p(\lambda_i \mid \mathbf{y}, \beta, \omega) &\propto p(\lambda_i, y_i, \beta, \omega) \\
&= p(\omega)p(\lambda_i)p(\beta \mid \omega)p(y_i|\beta, \omega, \lambda_i) \\
&\propto p(\lambda_i)p(y_i|\beta, \omega, \lambda_i) \\
&\propto \lambda_i^{h/2-1} \exp\left(-\lambda_i h/2\right) (\omega\lambda_i)^{1/2} \exp\left[-\frac{1}{2}\omega\lambda_i(X_i^T\beta - y_i)^2\right] \\
&\propto \text{Gamma}\left(\frac{h+1}{2}, \frac{1}{2}[h + \omega(X_i^T\beta - y_i)^2]\right)
\end{aligned}
$$
